SUMMARY

This program has the primary objective to conduct theoretical and experimental investigations of hot corrosion in Type 347 Stainless Steel and three other candidate materials. The term "hot corrosion" is defined herein to include oxidation, sulphidation, and carbon deposition. The investigations are to be carried out on small diameter, thin wall tubing (0.125 inches OD x 0.0035 inches wall thickness).

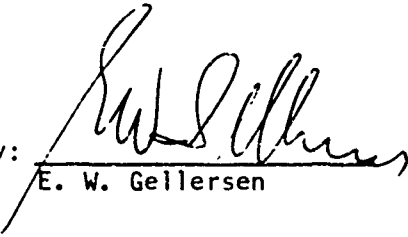

The initial tasks of the program, now complete, were to select base metal materials for tubing and brazing alloys for joining. The selection to be based on a theoretical analysis and evaluation of the candidate materials ability to resist hot corrosion at 1500°F.

The preliminary brazing tests, now complete except for microprobe analysis, consisted of metallographical evaluation of the brazed joints and a 100 hour static hot corrosion test. Materials selected are as follows:

<u>Tubing</u>	<u>Brazing Alloy</u>
Hastelloy X	Palniro 1 and J-8100
Incoloy 800	Palniro 7 and Coast Metals 50B
Multimet N-155	Palniro 1 and Microbraz 200
347 CRES	Palniro 7 and Microbraz 135

The cyclic-temperature hot corrosion tests, now in progress, are designed to develop stress rupture data from which two brazed base metal combinations can be selected for further testing in Phase II of the program. The test procedure and equipment is described and the initial data points are tabulated.

PRELIMINARY BRAZING TESTS

The objective of this task is to perform preliminary evaluation of candidate brazed tube-header specimens by metallography and static hot corrosion tests for the purpose of selecting two brazing filler metals for the four tubing materials to be further evaluated under Task D.

The preliminary brazing tests and evaluation were completed (except for the microprobe analysis) and the selection of brazing alloys for Task I-D was made based on the microstructures of the brazed joints and the results of the 100 hour hot corrosion test. The selection is as follows:

<u>TUBING</u>	<u>BRAZING ALLOY</u>
Hastelloy X	Palniro 1 J-8100
Incoloy 800	Palniro 7 Cost Metals 50B
N-155	Palniro 1 Microbraz 200
347 CRES	Palniro 7 Microbraz 135

Evaluation of Brazed Tube-Header Joints

Metallographical evaluation of the brazed joints was completed and the results are summarized in Tables I through V. Photomicrographs illustrating the brazing characteristics at each brazing temperature for all of the combinations of candidate brazing alloys and tubing materials are presented in Figures 1 through 20. N-155 and Hastelloy X had the best brazing characteristics for the brazing alloys used followed closely by Incoloy 800 and CRES 347. Although the Incoloy 300 had a dull surface appearance after brazing caused by oxidation, it still brazed fairly well. Inconel 625 had a surface appearance similar to that of Incoloy 800. Wetting and filleting, however, was poorer on Inconel 625.

Evaluation of Static Hot Corrosion Test Results

The one-inch long tube-header samples were sectioned longitudinally and their microstructures examined for the effects of the static hot corrosion test. Photomicrographs of the brazed joints in the unetched condition are shown in Figure 21 through 25 inclusive. These show the resistance of the various tube material/filler metal combinations to the corrosive atmospheres at 1500°F for 100 hours.

Figure 25. Photomicrographs of 347 CRES Tube-Header Joints Following Hot Corrosion Test at 1500°F for 100 Hours. The 347 CRES Tubing (1/8 in. O.D. x 0.0035 in. Wall) was Attacked to a Depth of Approximately 0.0015 in.

With the exception of the CRES 347, none of the other tube-header joints showed more than superficial corrosion. The stainless steel however was more heavily oxidized, as can be seen in Figure 25. Palniro 4, J-8100, Palniro 1, Palniro 7 and Microbraz 200 filler metals were not attacked by the sulphurous atmosphere. Microbraz 135 and Coast Metals 50B suffered moderate attack, but Microbraz 65 and Englehard 135 were both severely corroded.

Selection of Brazing Alloys for Task I-D Tests

The selection of two brazing alloys for each of the four candidate tubing materials for the cyclic-temperature stress-rupture tests in Task I-D was based on the following:

1. Brazing characteristics for each brazing alloy-tubing material combinations at the three temperatures used in brazing;
2. Effect of brazing temperature on tubing material;
3. Results of the 1500°F, 100 hour static hot corrosion tests;
4. Comparison of the best of the inexpensive nickel-base alloys with a more expensive gold-base alloy serves as a standard for comparison.

On the basis of the hot corrosion tests, Englehard 135 and Microbraz 65 were eliminated because of poor corrosion resistance. Coast Metals 50B and Microbraz 135 had satisfactory hot corrosion resistance and brazing characteristics, warranting consideration for the cyclic temperature tests. All the Palniro brazing alloys, J-8100, and Microbraz 200 had excellent hot corrosion resistance and brazing characteristics.

Both Palniro 4 and J-8100 were brazed at high temperatures (2175° and 2150°F, respectively), and grain growth occurred in base metals brazed at these temperatures. Grain coarsening, however, was more severe with Palniro 4. Very large grains are considered undesirable because of the possibility of decreased low cycle fatigue (LCF) resistance. In addition, Palniro 4 has no advantage over Palniro 1 (brazed at 2070°F) with respect to joint strength at 1300°F to 1500°F. Palniro 4 was therefore eliminated as a candidate.

The final selection is shown in Table VI.

TABLE VI. SELECTION OF BRAZING ALLOYS FOR TASK I-D		
Tubing	Brazing Alloy	Brazing Temperature, °F*
Hastelloy X	Palniro 1	2075
	J-8100	2150
Incoloy 800	Palniro 7	1950
	Coast Metals 50B	2050
N-155	Palniro 1	2075
	Nicrobraz 200	1950
347 CRES	Palniro 7	1950
	Nicrobraz 135	2000
*Hold time of 10 minutes, vacuum furnace brazing.		

The brazing alloys selected brazed well at all three brazing temperatures and should be satisfactory for production brazing of recuperators. The middle brazing temperature was selected for brazing with each alloy with a hold time of 10 minutes at brazing temperature. The brazing alloys selected are further discussed for each of the tubing materials:

- Hastelloy X - Palniro 1 had excellent brazing characteristics as noted in Table I. It also had excellent hot corrosion resistance. The 2075°F brazing temperature will permit retention of a fine grained structure. The J-8100 had good brazing characteristics and excellent hot corrosion resistance. Alloying was greater with J-8100 than Palniro 1 but still satisfactory. Grain growth occurred in Hastelloy X when brazing with J-8100. A fine grained structure has better tensile and fatigue properties, but lower stress-rupture properties. Selection of these two brazing alloys will afford a comparison between fine and coarse grain material in Task I-D tests. These two brazing alloys have previously been evaluated for a similar application in a lightweight heat exchanger operating at 1540°F maximum temperature. Both alloys performed equally well in axial tensile and axial fatigue tests at room temperature and 1540°F. Failures occurred in the tubing (1/8 in. O.D. x 0.003 in. wall) away from the brazed joint.
- Incoloy 800 - The basis for selecting Palniro 7 for Incoloy 800 was excellent brazing characteristics, hot corrosion resistance, and retention of a fine grain structure. Coast Metals 50B permitted some grain growth in Incoloy 800, alloyed somewhat more than Nicrobraz 135, but penetrated less than Nicrobraz 135. Within the brazing temperature evaluated, Coast Metals 50B had less overall alloying and penetration with Incoloy 800 than Nicrobraz 135 and was selected as a second choice.

- N-155 - Palniro 1 had good brazing characteristics and excellent hot corrosion resistance. It was selected for brazing N-155 for the same reasons as for brazing Hastelloy X. Microbraz 200 also had good brazing characteristics and excellent hot corrosion resistance. Alloying and penetration of the N-155 by Microbraz 200 was only about 0.001 in. which should be satisfactory for this application.
- 347 CRES - Palniro 7 was an obvious first choice because of its excellent brazing characteristics and hot corrosion resistance. Microbraz 135 and Coast Metals 50B had similar brazing characteristics and hot corrosion resistance. Because of its lower brazing temperature, the Microbraz 135 (2000°F) would be more compatible with the annealing temperature of 347 CRES (1950°F maximum) than 50B (2050°F). Grain size of the 347 tubing was larger for the 50B brazing cycle than the Palniro 7 cycle. Microbraz 135 was selected as the second choice.

Evaluation of Inconel 625 Tubing

Inconel 625 was originally selected for the program because its chemical composition and mechanical strength is similar to Hastelloy X, indicating that its service life would be similar. However, the former material has important advantages in ductility and price. These are important criteria in recuperator design because ductility is reflected in good low cycle fatigue resistance (thermal fatigue resistance) and manufacturing economics. The low price of Inconel 625 (about 43 percent of the cost of Hastelloy X) makes it a particularly attractive high temperature recuperator material.

The first consignment of tubing to be received was found to contain numerous longitudinal cracks which rendered the material unsuitable for stress-rupture testing. During December a second batch of material was delivered and this too suffered from surface defects. Microstructural examination revealed what appeared to be foreign particles impressed into the surface of both the inner and outer wall of the tubing to a depth of about 0.0005 inch (Figure 26). These particles were not identified. It appeared that alloying occurred between the particles and the Inconel 625 during annealing. Because these areas could seriously affect the performance of the Inconel 625 in the stress-rupture tests, this second shipment of tubing was also considered unsatisfactory, and no additional brazing studies were carried out with this material.

The supplier was requested to analyze this tubing and his report confirmed that O.D. surface imperfections were widespread. His search for contamination was hampered by difficulty in etching without severe attack or staining and as a result none was identified. However, by a review of the manufacturing process, the test records, and micro examination, he concluded that the contamination occurred in finish processing. He also concluded that its unusual nature suggested an isolated occurrence and reoccurrence improbable. The program could not wait for a new supply of tubing, therefore Hastelloy X was made ready for test.

Figure 26. Inconel 625 Tube Wall Section

F-9001

CYCLIC-TEMPERATURE HOT-CORROSION TESTS

The object of this task is to develop stress-rupture data which, when analyzed with the engine and recuperator design data given in the contract schedule, will lead to a selection of two tube material candidates for test in a combustor exhaust environment under Phase II of the program.

Tubing made from four materials (Hastelloy X, Inconel 800, Multimet N-55, CRES 347), each brazed with two different filler alloys, subject to a cyclic corrosive environment, will be pressurized at various levels to produce failure in approximately 75, 300 and 1000 hours. The tests are being conducted in three Marshall furnaces set-up as shown in Figure 27, maintaining metal temperatures of 1100, 1300 and 1500°F.

All samples of each material combination, required for testing, have been prepared in triplicate. Some difficulty was encountered in automating the test equipment to control the gas flow and thermal cycle so that an overshoot in temperature would not occur. The electronic equipment initially selected to guard against an over temperature condition was found to interfere with normal control and had to be replaced. Testing began the last week in January after this condition was remedied.

Test Cycle

Schematic diagrams, Figures 28 through 32, show the test cycle plan and test hardware arrangement. The tube samples, shown fitted to a header plate in Figure 33, are confined within a stainless steel retort which itself is enclosed by a Marshall furnace. The test gas enters at the top of the retort, flows parallel with the tube bodies, and leaves at the bottom through the header plate to be vented to atmosphere.

A sea salt solution is injected into the gas stream, at the top of the retort, at a controller rate to maintain a concentration of 5 ppm sea salts in the gases. The sea salt solution was prepared in accordance with Specification ASTM D665-60 Procedure B shown in Table VII. The temperature cycle consists of two and a quarter hours at temperature, cooling down 500 to 600°F in one minute, six minutes temperature recovery and repeat. Oxidizing gas (4 percent CO₂, 15 percent O₂, 81 percent N₂ and 150 ppm SO₂) is flowing for two hours up to the point of the cycle where cooling begins. Liquid nitrogen is used to effect the temperature drop. A reducing gas (3.5 percent CO₂, 10 percent CO, 77.5 percent N₂, and 350 ppm H₂S) is passed over the tubes during the temperature recovery period. Pure nitrogen is then passed through the retort for fifteen minutes to purge the system before the oxidizing gas is again admitted.

The tubes are pressurized with nitrogen gas containing one percent oxygen. Air was not chosen for this purpose because of the potentially explosive situation which would arise if tube rupture occurred during the reducing cycle. Yet, some oxygen is required to cause oxidation on the inside surfaces of the tubes to simulate more closely the service conditions of recuperators. Pure nitrogen might result in formation of surface-nitrides,

particulaly in aluminum and titanium bearing alloys. Previous experience at AiResearch has indicated that the chosen gas contains sufficient oxygen to produce the desired effect.

Test Results

A tabulation of results obtained to date can be found in Table VIII through XI. These initial points were plotted and compared against published sheet material stress rupture data so that pressure loadings for subsequent testing could be selected. An examination of these tables shows that, at 1500°F, most all samples tested at the high stress level failed earlier than planned, and that there is a wide scatter of results at the lower stress level. This is believed to be a result of a more severe corrosion condition existing at this temperature level than initially anticipated. Metallographic examination is being undertaken to conform this belief. Testing is continuing and is planned to be complete by mid June 1968.
